

Single and Double Alkyl Abstraction from a
Bis(anilido)xanthene Thorium(IV) Dibenzyl Complex:
Isolation of an Organothorium Cation and a Thorium
Dication

Introduction and Results and Discussion

Organometallic complexes of the early transition metals and lanthanides have received considerable recent attention, in no small part due to their proficiency as catalysts for transformations such as olefin polymerization, hydrogenation, and hydroamination.¹ Over the course of these studies, complexes supported by non-carbocyclic ancillary ligands have played an increasingly prominent role, providing a wide variety of metal-binding environments that contrast those provided by cyclopentadienyl anions, and allowing facile tuning of both steric and electronic properties.² By contrast, the vast majority of organoactinide(IV) chemistry has involved neutral complexes bearing carbocyclic (e.g. C₅R₅⁻ or C₈R₈²⁻) ancillaries.³

A major current focus of our research is investigation of the potential for rigid non-carbocyclic ligands to stabilize neutral and cationic organothorium(IV) and uranium(IV) complexes.^{4,5} Such complexes are anticipated to be particularly reactive as a result of tetravalency (in contrast with predominantly trivalent Group 3 and lanthanide metals) combined with the electropositive nature and large ionic radii of early actinides. The potential for covalency and f-orbital participation in early actinide metal-ligand bonding can also lead to reactivity that deviates substantially from that of related transition metal and lanthanide complexes.⁶

SCHEME 1

Herein we report the synthesis of a dibenzyl thorium complex, [(XA₂)Th(CH₂Ph)₂] (**1**; XA₂ = 4,5-bis(2,6-diisopropylanilido)-2,7-di-*tert*-butyl-9,9-dimethylxanthene),^{4,7} followed by reaction of **1** with either one or two equivalents of B(C₆F₅)₃ to give the first non-cyclopentadienyl actinide alkyl cation, and the first example of double alkyl abstraction to form an actinide dication.

Reaction of [(XA₂)ThCl₂(dme)]⁴ with two equivalents of benzyl magnesium chloride at -78 °C resulted in the formation of base-free [(XA₂)Th(CH₂Ph)₂] (**1**)⁷ as a hexane soluble light yellow solid in 56% yield. At

50 °C, the ^1H NMR of **1** is suggestive of C_{2v} symmetry. However, at below –40 °C, a spectrum consistent with a C_s symmetric complex lacking top-bottom symmetry and containing two distinct benzyl groups is observed.⁸ The $^1J_{\text{C},\text{H}}$ coupling constants of 120 and 139 Hz for CH_2Ph indicate that one benzyl group is η^1 -coordinated, while the other adopts an η^2 - or η^3 -coordination mode.⁹

X-ray quality crystals of **1** were grown from hexanes at –30 °C. The unit cell contains two distinct molecules of **1** [$\text{Th}-\text{CH}_2 = 2.503(3)$ - $2.545(3)$ Å], and in both cases, one benzyl group is located in the ligand plane while the other occupies an apical site. For both molecules, the in-plane benzyl group adopts a bonding mode intermediate between η^2 - and η^3 -coordination [$\text{Th}-\text{CH}_2-\text{C}_{ipso} = 85.6(2)$ and $87.5(2)^\circ$; $\text{Th}-\text{C}_{ipso} = 2.826(3)$ and $2.851(3)$ Å; $\text{Th1}-\text{C}_{ortho} = 3.191(3)$ and $3.510(3)$ Å; $\text{Th2}-\text{C}_{ortho} = 3.126(4)$ and $3.647(4)$ Å].¹⁰ By contrast, the apical benzyl group is η^1 -coordinated in one molecule [$\text{Th1}-\text{CH}_2-\text{C}_{ipso} = 115.1(2)^\circ$; $\text{Th1}-\text{C}_{ipso} = 3.402(3)$ Å], but approaches η^2 -coordination in the other [$\text{Th2}-\text{CH}_2-\text{C}_{ipso} = 96.1(2)^\circ$; $\text{Th2}-\text{C}_{ipso} = 3.058(3)$ Å].⁹

FIGURE 1

Slow addition of dibenzyl complex **1** to one equivalent of $\text{B}(\text{C}_6\text{F}_5)_3$ in hexanes resulted in the immediate precipitation of $[(\text{XA}_2)\text{Th}(\text{CH}_2\text{Ph})][\text{PhCH}_2\text{B}(\text{C}_6\text{F}_5)_3]$ (**2**) as a bright yellow solid in 95% yield. Despite numerous attempts, X-ray quality crystals of **2** were not obtained. However, the nature of **2** was established by NMR spectroscopy, elemental analysis and reactivity (vide infra). The only other actinide alkyl cations are $[(\text{C}_5\text{Me}_5)_2\text{ThMe}(\text{THF})_n]^+$ ($n = 0, 1$ or 2) reported by Marks *et al.* paired with a variety of bulky non-coordinating anions,¹¹ and $[(\text{C}_5\text{Me}_5)_2\text{UMe}(\text{THF})][\text{BPh}_4]$ reported by Evans *et al.*¹² Solution NMR data for **2** between 50 and –90 °C are commensurate with a C_s symmetric complex lacking top-bottom symmetry.⁸ These data, as well as the high solubility of **2**, indicate tight ion pairing, presumably through π -coordination of the anion. Evidence for this coordination mode is provided by a

$\Delta\delta_{m-p}$ value of 3.93 ppm in the ^{19}F NMR spectrum, the upfield position of the *m*-BCH₂*Ph* protons (5.98 ppm), and the downfield shift of the *ipso*-BCH₂*Ph* carbon (162.9 ppm) relative to that of the ‘free’ anion (148.2 ppm). Through space coupling between the *o*- and *m*-BCH₂*Ph* protons and one of the CH*Me*₂ groups was also observed by 2D-ROESY NMR spectroscopy. The benzyl group on thorium is η^1 -coordinated, based on a $^1J_{\text{C},\text{H}}$ value of 119 Hz for ThCH₂Ph.⁹

Slow diffusion of a hexane solution of B(C₆F₅)₃ into a toluene solution of **2** at -30 °C resulted in precipitation of a bright orange crystalline solid. Solution NMR spectroscopic studies on this product were not possible due to insolubility in solvents with which it did not react. However, the complex was identified as dicationic [(XA₂)Th][PhCH₂B(C₆F₅)₃]₂ (**3**; Figure 1) by X-ray crystallography and elemental analysis.¹³

The solid state structure of **3** is shown in Figure 2. The XA₂ backbone is approximately planar and the benzyl borate anions are π -coordinated to thorium both in the ligand plane and in the apical site, with Th-C(X) bond distances increasing in the order C(X) = C_{para} < C_{meta} < C_{ortho} < C_{ipso} [from 2.900(7) to 3.280(7) Å and 2.937(6) to 3.257(7) Å for the borate anions in the ligand plane and the apical site respectively]. To minimize unfavorable steric interactions between benzylborate anions and ligand isopropyl groups, the thorium atom resides 0.908(6) Å above the plane defined by the NON-donor atoms, and the 2,6-diisopropylphenyl groups are rotated to give C(30)…C(45) and C(33)…C(42) distances of 4.139(12) and 8.531(11) Å respectively.

FIGURE 2

Double alkyl, aryl or hydride abstraction has only been observed in a handful of cases,¹⁴⁻¹⁷ and the resulting dications are typically stabilized by additional Lewis base (O-, N-, or P-donor) coordination. To the best of our knowledge, the only other ‘Lewis base free’ dications formed by this method are

$[(t\text{Bu}_3\text{PN})_2\text{Ti}]X_2$,¹⁵ $[(\text{nacnac})\text{Sc}]X_2$,¹⁶ and $[(\text{C}_5\text{H}_4\text{CMe}_2\text{Ph})_2\text{Zr}]X_2$ ¹⁷ where X is the $\text{MeB}(\text{C}_6\text{F}_5)_3$ anion, and $[\text{LSc}(\text{CH}_2\text{SiMe}_3)][\text{B}(\text{C}_6\text{F}_5)_4]_2$ generated *in situ* and characterized by NMR spectroscopy ($\text{L} = 1,1,1\text{-tris}[(S)\text{-}4\text{-isopropylloxazolinyl}]$ ethane)¹⁸ or suggested on the basis of extremely high 1-hexene polymerization activity ($\text{L} = 1,4,7\text{-trithiacyclononane}$).¹⁹

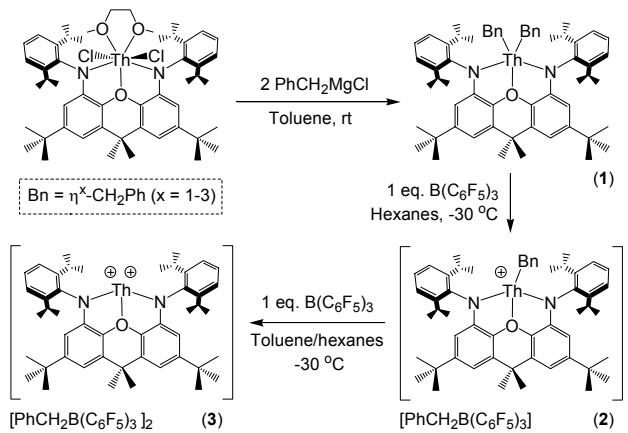

Dibenzyl complex **1** and mono-cation **2** were tested as catalysts for ethylene polymerization under 1 atmosphere of C_2H_4 at 25 and 60 °C. However, polymer formation was not observed, even after 24 hours, presumably due to the ability of thorium to engage in strong π -arene coordination, despite flanking of the metal with bulky *N*-(2,6-diisopropylphenyl) groups. Future work will focus on the reactivity of **2** with various unsaturated substrates, including alkenes under more forcing conditions. Bis(anilido)xanthene thorium alkyl cations with a reduced tendency towards arene coordination will also be pursued.

Single and Double Alkyl Abstraction from a Bis(anilido)xanthene Thorium(IV) Dibenzyl Complex:
Isolation of an Organothorium Cation and a Thorium Dication

Carlos A. Cruz, David J. H. Emslie,* Laura E. Harrington and James F. Britten

Summary: Reaction of $[(XA_2)\text{ThCl}_2(\text{dme})]$ [$XA_2 = 4,5\text{-bis}(2,6\text{-diisopropylanilido)-}2,7\text{-di-}tert\text{-butyl-}$ 9,9-dimethylxanthene] with two equivalents of PhCH_2MgCl at resulted in the formation of solvent-free $[(XA_2)\text{Th}(\text{CH}_2\text{Ph})_2]$ (**1**). Subsequent reaction of **1** with either one or two equivalents of $\text{B}(\text{C}_6\text{F}_5)_3$ allowed isolation of the first non-cyclopentadienyl actinide alkyl cation, $[(XA_2)\text{Th}(\text{CH}_2\text{Ph})][\text{PhCH}_2\text{B}(\text{C}_6\text{F}_5)_3]$ (**2**) and a rare example of an actinide dication, $[(XA_2)\text{Th}][\text{PhCH}_2\text{B}(\text{C}_6\text{F}_5)_3]_2$ (**3**). The X-ray crystal structure of the dication reveals π -coordination of both $\text{PhCH}_2\text{B}(\text{C}_6\text{F}_5)_3$ anions, and solution NMR spectroscopy shows that a similar mode of contact ion pairing is operative in the monocation.
